Abstract
Mercury is a sequential satisficing planner that is based mainly on the red-black planning heuristic. Red-black planning is a systematic approach to partial delete relaxation, taking into account some of the delete effects: Red variables take the relaxed (value-accumulating) semantics, while black variables take the regular semantics. Prior work on red-black plan heuristics has identified a powerful tractable fragment requiring the black causal graph—the projection of the causal graph onto the black variables—to be a DAG; but all implementations so far use a much simpler fragment where the black causal graph is required to not contain any arcs at all. We close that gap here, and we design techniques aimed at making red-black plans executable, short-cutting the search. Mercury planner is entered into sequential satisficing and agile tracks of the competition.

Planner structure
Mercury planner is a sequential satisficing planner that is implemented in the Fast Downward planning system (Helmert 2006). It performs multiple iterations of heuristic search, starting with a fast and inaccurate greedy best-first search. Once a solution is found, next iterations run weighted \( A^* \), gradually decreasing the weight parameter, similarly to the famous LAMA planning system (Richter and Westphal 2010). The cost of the best plan found so far is used in following iterations for search space pruning. Search algorithms are guided by the red-black heuristic (Katz, Hoffmann, and Domshlak 2013b; 2013a; Katz and Hoffmann 2013), breaking ties using the landmark count heuristic (Porteous, Sebastia, and Hoffmann 2001). In addition, preferred operators are obtained from each of those heuristics. For red-black heuristic, which is based on FF (Hoffmann and Nebel 2001), we decided to use here the preferred operators of FF heuristic. As the rest of the components are well known, in what follows, we describe in detail the main novelty of Mercury, red-black heuristic.

Introduction
The delete relaxation, where state variables accumulate their values rather than switching between them, has played a key role in the success of satisficing planning systems, e.g. (Bonet and Geffner 2001; Hoffmann and Nebel 2001; Richter and Westphal 2010). Still, the delete relaxation has well-known pitfalls, for example the fundamental inability to account for moves back and forth (as done, e.g., by vehicles in transportation). It has thus been an actively researched question from the outset how to take some deletes into account, e.g. (Fox and Long 2001; Gerevini, Saetti, and Serina 2003; Helmert 2004; Helmert and Geffner 2008; Baier and Botea 2009; Cai, Hoffmann, and Helmert 2009; Haslum 2012; Keyder, Hoffmann, and Haslum 2012). Herein, we continue the most recent attempt, red-black planning (Katz, Hoffmann, and Domshlak 2013b; 2013a; Katz and Hoffmann 2013) where a subset of red state variables takes on the relaxed value-accumulating semantics, while the other black variables retain the regular semantics.

Katz et al. (2013b) introduced the red-black framework and conducted a theoretical investigation of tractability. Following up on this (2013a), they devised practical red-black plan heuristics, non-admissible heuristics generated by repairing fully delete-relaxed plans into red-black plans. Observing that this technique often suffers from dramatic overestimation incurred by following arbitrary decisions taken in delete-relaxed plans, Katz and Hoffmann (2013) refined the approach to rely less on such decisions, yielding a more flexible algorithm delivering better search guidance.

The black causal graph is the projection of the causal graph onto the black variables only. Both Katz et al. (2013a) and Katz and Hoffmann (2013) exploit, in theory, a tractable fragment characterized by DAG black causal graphs, but confine themselves to arc-empty black causal graphs – no arcs at all – in practice. Thus current red-black plan heuristics are based on a simplistic, almost trivial, tractable fragment of red-black planning. We herein close that gap, designing red-black DAG heuristics exploiting the full tractable fragment previously identified. To that end, we augment Katz and Hoffmann’s implementation with a DAG-planning algorithm (executed several times within every call to the heuristic function). We devise some enhancements targeted at making the resulting red-black plans executable in the real task, stopping the search if they succeed in reaching the goal.

Background
Our approach is placed in the finite-domain representation (FDR) framework. We introduce FDR and its delete-relaxation as special cases of red-black planning. A red-
black (RB) planning task is a tuple II = \( (V^B, V^R, A, I, G) \). 
\( V^B \) is a set of black state variables and \( V^R \) is a set of red 
state variables, where \( V^B \cap V^R = \emptyset \) and each \( v \in V := 
V^B \cup V^R \) is associated with a finite domain \( \mathcal{D}(v) \). The initial 
state \( I \) is a complete assignment to \( V \), the goal \( G \) is a partial 
assignment to \( V \). Each action \( a \) is a pair \( (\text{pre}(a), \text{eff}(a)) \) of 
partial assignments to \( V \) called precondition and effect. 

We often refer to (partial) assignments as sets of facts, i.e., 
variable-value pairs \( v = d \). For a partial assignment \( p \), \( \mathcal{V}(p) \) 
denotes the subset of \( V \) instantiated by \( p \). For \( V' \subseteq \mathcal{V}(p) \), 
\( p[V'] \) denotes the value of \( V' \) in \( p \).

A state \( s \) assigns each \( v \in V \) a non-empty subset 
\( s[v] \subseteq \mathcal{D}(v) \), where \( |s[v]| = 1 \) for all \( v \in V^B \). An action 
\( a \) is applicable in state \( s \) if \( \text{pre}(a)[v] \subseteq \mathcal{S}(a)[v] \) for \( v \in \mathcal{V}(a) \). Applying \( a \) in \( s \) changes the value of 
\( v \in \mathcal{V}(\text{eff}(a)) \cap V^B \) to \( \text{eff}(a)[v] \), and changes the value of 
\( v \in \mathcal{V}(\text{eff}(a)) \cap V^R \) to \( s[v] \cup \text{eff}(a)[v] \). By 
\( s[\{a_1, ..., a_k\}] \) we denote the state obtained from sequential application 
of \( a_1, ..., a_k \). An action sequence \( (a_1, ..., a_k) \) is a plan if 
\( G[v] \in \mathcal{F}[\{a_1, ..., a_k\}] \) for all \( v \in \mathcal{G}(\Pi) \).

II is a finite-domain representation (FDR) planning task if \( V^R = \emptyset \), 
and is a monotonic finite-domain representation (MFDR) planning task 
if \( V^B = \emptyset \). Plans for MFDR tasks (i.e., for delete-relaxed tasks) can be generated 
in polynomial time. A key part of many satisficing planning 
systems is based on exploiting this property for deriving 
heuristic estimates, via delete-relaxing the task at hand. 

Generalizing this to red-black planning, the red-black 
relaxation of an FDR task II to \( V^R = \emptyset \) is the RB task 
\( II^+ = (V \setminus V^R, V^R, A, I, G) \). A plan for \( II^+ \) is a red-black 
plan for II, and the length of a shortest possible red-black plan is denoted \( h^+_{\text{rb}}(\Pi) \). For arbitrary states \( s \), 
\( h^+_{\text{rb}}(s) \) is defined via the RB task \( (V \setminus V^R, V^R, A, s, G) \). If \( V^R = V \), 
then red-black plans are relaxed plans, and \( h^+_{\text{rb}} \) coincides 
with the optimal delete relaxation heuristic \( h^+ \).

![Figure 1: An example (a), and its causal graph (b).](image)

In Figure 1, truck \( T \) needs to transport each package \( X \in \{A, B, C\} \) to its respective goal location \( x \in \{a, b, c, d\} \). 
The truck can only carry one package at a time, encoded 
by a Boolean variable \( F \) ("free"). A real plan has length 
15 (8 loads/unloads, 7 drives), a relaxed plan has length 12 
(4 drives suffice as there is no need to drive back). If we 
paint (only) \( T \) black, then \( h^+_{\text{rb}}(I) = 15 \) as desired, but red-black 
plans may not be applicable in the real task, because \( F \) is still red so we can load several packages consecutively. 
Painting \( T \) and \( F \) black, that possibility disappears.\(^1\)

\(^1\)Indeed, all optimal red-black plans (but not some non-optimal 
oneas) are real plans. We will get back to this below: As we 
shall see, the ability to increase red-black plan applicability is a

Tractable fragments of red-black planning have been 
identified using standard structures. The causal graph \( CG_{\Pi} \) 
of \( \Pi \) is a digraph with vertices \( V \). An arc \( (v, v') \) is in 
\( CG_{\Pi} \) if \( v \neq v' \) and there exists an action \( a \in A \) such that 
\( (v, v') \in [\mathcal{V}(\text{eff}(a)) \cup \mathcal{V}(\text{pre}(a))] \times \mathcal{V}(\text{eff}(a)) \). The domain 
transit graph \( DTG_{\Pi}(v) \) of a variable \( v \in V \) is a labeled 
digraph with vertices \( \mathcal{D}(v) \). The graph has an arc \((d, d')\) 
defined by action \( a \) if \( \text{eff}(a)[v] = d' \), and either \( \text{pre}(a)[v] = d \) 
or \( v \notin \mathcal{V}(\text{pre}(a)) \). The arc is labeled with its outside condition 
\( \text{pre}(a)[V \setminus \{v\}] \) and its outside effect \( \text{eff}(a)[V \setminus \{v\}] \).

The black causal graph \( CG^B_{\Pi} \) of II is the subgraph 
of \( CG_{\Pi} \) induced by \( V^B \). An arc \((d, d')\) is relaxed sides effects 
invertible, RSE-invertible for short, if there exists an arc 
\((d', d)\) with outside condition \( \phi' \subseteq \phi \cup \psi \) where \( \phi \) and \( \psi \) 
are the outside condition respectively outside effect of \( (d, d') \). 
A variable \( v \) is RSE-invertible if all arcs in \( DTG^B_{\Pi}(v) \) are RSE-
invertible, and an RB task is RSE-invertible if all its black variables are. 
Prior work on red-black plan heuristics (Katz, Hoffmann, and Domshlak 2013a; Katz and Hoffmann 2013) 
proved that plan generation for RSE-invertible RB tasks with 
DAG (acyclic) black causal graphs is tractable, but used 
the much simpler fragment restricted to arc-empty black causal 
graphs in practice. In Figure 1, both \( T \) and \( F \) are RSE-
invertible; if we paint only \( T \) black then the black causal 
graph is arc-empty, and if we paint both \( T \) and \( F \) black then 
the black causal graph is (not arc-empty but) a DAG.

**Red-Black DAG Heuristics**

Katz and Hoffmann (2013) provide an algorithm for RSE-
invertible RB tasks with acyclic black causal graphs. To 
provide the context, Figure 2 shows Katz and Hoffmann’s 
pseudo-code. The algorithm assumes as input the set \( R^+ \) 
of preconditions and goals on red variables in a fully 
delete-relaxed plan, i.e., \( R^+ = \mathcal{G}[\mathcal{V}] \cup \bigcup_{a \in \pi} \mathcal{V}(\text{pre}(a)) \) where 
\( \pi^+ \) is a relaxed plan for II. It then successively selects 
achieving actions for \( R^+ \), until all these red facts are true. 
Throughout the algorithm, \( R \) denotes the set of red facts 
already achieved by the current red-black plan prefix \( \pi \); \( B \) 
denotes the set of black variable values that can be achieved 
using only red outside conditions from \( R \).

For each action \( a \in A' \) selected to achieve new facts from 
\( R^+ \), and for the global goal condition at the end, 
there may be black variables that do not have the required values. 
For example, say we paint \( T \) and \( F \) black in Figure 1. Then \( R^+ \) 
will have the form \( \{A = T, A = a, B = T, B = b, C = T, C = c, D = T, D = d\} \). 
In the initial state, \( A' \) will contain only load actions. Say we execute \( a = \text{load}(A, \text{init}) \), 
entering \( A = T \) into \( R \) and thus including unload \((A, a) \) into \( A' \) 
in the next iteration. Trying to execute that action, we 
find that its black precondition \( T = a \) is not satisfied. 
The call to \( ACHIEVE\{\{T = a\}\} \) is responsible for rectifying this. 
\( ACHIEVE(g) \) creates a task \( II^B \) over II’s black variables, 
asking to achieve \( g \). As Katz and Hoffmann showed, \( II^B \) 
is solvable, has a DAG causal graph, and has strongly 
connected DTGs (when restricting to actions \( a \) where \( \text{pre}(a) \subseteq I[I[\pi]] \)). From this and Theorem 4.4 of Chen and Gimenez

main advantage of our red-black DAG heuristics over the simpler 
red-black plan heuristics devised in earlier work.
Algorithm:\ RedBlackPlanning\( (\Pi, R^+)\)
main
\[\Pi = (V^B, V^R, A, I, G)\]
global \(R, B \leftarrow \emptyset, \pi \leftarrow \emptyset\)
UPDATE()
while \(R \supseteq R^+\)
\[A' = \{a \in A \mid \text{pre}(a) \subseteq B \cup R, \text{eff}(a) \cap (R^+ \setminus R) \neq \emptyset\}\]
\begin{enumerate}
  \item Select \(a \in A'\)
  \item if \(\text{pre}(a)[V^B] \not\subseteq I[\pi]\)
     \begin{enumerate}
       \item then \(\pi \leftarrow \pi \circ \text{ACHIEVE}(\text{pre}(a)[V^B])\)
       \item UPDATE()
     \end{enumerate}
  \end{enumerate}
if \(G[V^B] \not\subseteq I[\pi]\)
\(\pi \leftarrow \pi \circ \text{ACHIEVE}(G[V^B])\)
return \(\pi\)

procedure UPDATE()
\(R \leftarrow I[\pi][V^R]\)
\(B \leftarrow B \cup I[\pi][V^B]\)
for \(v \in V^B\) ordered topologically by the black causal graph
\(B \leftarrow B \cup \text{DTG}(v)[R \cup B]\)

procedure ACHIEVE\((g)\)
\(I^B \leftarrow I[\pi][V^B]\)
\(G^B \leftarrow g\)
\(A^B \leftarrow \{a^B \mid a \in A, a^B = (\text{pre}(a)[V^B], \text{eff}(a)[V^B]), \text{pre}(a) \subseteq R \cup B, \text{eff}(a)[V^B] \subseteq B\}\)
\(\langle a_1^B, \ldots, a_k^B \rangle \leftarrow \text{an FDR plan for } \Pi^B = (V^B, A^B, I^B, G^B)\)
return \(\langle a_1^B, \ldots, a_k^B \rangle\)

Figure 2: Red-black planning algorithm. \(R^+ = G[V^R] \cup \bigcup_{a \in \pi^+} \text{pre}(a)[V^R]\) where \(\pi^+\) is a relaxed plan for \(\Pi\).

(2010), it directly follows that a plan for \(\Pi^B\), in a succinct plan representation, can be generated in polynomial time.

The “succinct plan representation” just mentioned consists of recursive macro actions for pairs of initial-value/other-value within each variable’s DTG; it is required as plans for \(\Pi^B\) may be exponentially long. Chen and Gimenez’ algorithm handling these macros involves the exhaustive enumeration of shortest paths for the mentioned value pairs in all DTGs, and it returns highly redundant plans moving preconditions variables back to their initial value in between every two requests. For example, if a truck unloads two packages at the same location, then it is moved back to its start location in between the two unload actions.

Katz and Hoffmann (2013) simplified the complexity of DAG planning, and considered \(\Pi^B\) with arc-empty causal graphs, solving which is trivial. In our work, after exploring a few options, we decided to use the simple algorithm in Figure 3: Starting at the leaf variables and working up to the roots, the partial plan \(\pi^B\) is augmented with plan fragments bringing the supporting variables into place (a similar algorithm was mentioned, but not used, by Helmert (2006)).

**Proposition 1** The algorithm DAPLAN\((\Pi^B)\) is sound and complete, and its runtime is polynomial in the size of \(\Pi^B\) and the length of the plan \(\pi^B\) returned.

Note here that the length of \(\pi^B\) is worst-case exponential in the size of \(\Pi^B\), and so is the runtime of

Algorithm:\ DAPLAN\((\Pi^B)\)
main
\(\pi^B \leftarrow \emptyset\)
for \(i = n \text{ downto } 1\)
\(\Pi^B \leftarrow \{a_1, \ldots, a_k\}\)
\(d \leftarrow I[v_i]\)
for \(j = 1 \text{ to } k\)
\begin{enumerate}
  \item if \(\text{pre}(a_j)[v_i]\) is defined
  \begin{enumerate}
    \item then \(\pi_j \leftarrow \pi \circ \text{pre}(a_j)[v_i]\)
    \item \(d \leftarrow \text{pre}(a_j)[v_i]\)
  \end{enumerate}
  \item if \(G[v_i]\) is defined
  \begin{enumerate}
    \item then \(\pi_{k+1} \leftarrow \pi_{k+1} \circ G[v_i]\)
    \item \(\pi_{k+1} \leftarrow \pi_{k+1} \circ d\)
  \end{enumerate}
\end{enumerate}
return \(\pi^B\)

Figure 3: Planning algorithm for FDR tasks \(\Pi^B\) with DAG causal graph \(CG_{\Pi^B}\) and strongly connected DTGs. \(v_1, \ldots, v_n\) is an ordering of variables \(V\) consistent with the topology of \(CG_{\Pi^B}\). \(\pi_v(d, d')\) denotes an action sequence constituting a shortest path in \(\text{DTG}(\Pi)\) from \(d\) to \(d'\).

DAPLAN\((\Pi^B)\). We trade the theoretical worst-case efficiency of Chen and Gimenez’ algorithm against the practical advantage of not having to rely on exhaustive computation of shortest paths anew for every call of DAPLAN\((\Pi^B)\), with “initial values” and DTGs from \(\Pi^B\) for input tasks \(\Pi^B\) that typically have small plans (achieving the next action’s black preconditions) anyhow.

Unlike the macro-based algorithm of Chen and Gimenez, our DAPLAN\((\Pi^B)\) algorithm does not superfluously keep switching supporting variables back to their initial values. But it is not especially clever, either: If variable \(v_0\) supports two otherwise independent leaf variables \(v_1\) and \(v_2\), then the sub-plans for \(v_1\) and \(v_2\) will be inserted sequentially into \(\pi^B\), losing any potential for synergies in the values of \(v_0\) required.

**Painting Strategy**

Katz and Hoffmann explored a variety of painting strategies, i.e., strategies for selecting the black variables. We kept this simple here because, as we noticed, there actually is little choice, at least when accepting the rationale that we should paint black as many variables as possible: In most IPC domains, there are at most 2 possible paintings per task. To illustrate, consider Figure 1: We can paint \(T\) and \(F\) black, or paint \(T\) and the packages black. All other paintings either do not yield a DAG black causal graph, or are not set-inclusion maximal among such paintings. We thus adopted one of Katz and Hoffmann’s basic strategies, namely ordering the variables by causal graph level, and iteratively painting variables red until the black causal graph is a DAG (Katz and

---

\(^2\)One could estimate DAG plan length (e.g., using Helmert’s (2006) causal graph heuristic), computing a red-black plan length estimate only. But that would forgo the possibility to actually execute DAG red-black plans, which is a key advantage in practice.
Hoffmann’s original strategies continue until that graph is arc-empty).

**Enhancing Red-Black Plan Applicability**

One crucial advantage of red-black plans, over fully-delete relaxed plans, is that they have a much higher chance of actually working for the original planning task. This is especially so for the more powerful DAG red-black plans we generate here. In Figure 1, as already mentioned, if we paint just \( T \) black then the red-black plan **might** work; but if we paint both \( T \) and \( F \) black – moving to a non-trivial DAG black causal graph – then **every optimal red-black plan definitely works**. A simple possibility for exploiting this, already implemented in Katz and Hoffmann’s (2013) earlier work, is to **stop search** if the red-black plan generated for a search state \( s \) is a plan for \( s \) in the original task.

There is a catch here, though – the red-black plans we generate are not optimal and thus are not guaranteed to execute in Figure 1. In our experiments, we observed that the red-black plans often were not executable due to simple reasons. We fixed this by augmenting the algorithms with the two following applicability enhancements.

1. Say that, as above, \( R^+ = \{ A = T, A = a, B = T, B = b, C = T, C = c, D = T, D = d \} \) and REDBLACKPLANNING started by selecting load \((A, init)\). Unload \((A, a)\) might be next, but the algorithm might just as well select load \((B, init)\). With \( T \) and \( F \) black, load \((B, init)\) has the black precondition \( F = true \). Calling ACHIEVE \((F = true)\) will obtain that precondition using unload \((A, init)\). Note here that variable \( A \) is red so the detrimental side effect is ignored. The same phenomenon may occur in any domain with renewable resources (like transportation capacity). We tackle it by giving a preference to actions \( a \in A' \) getting whose black preconditions does not involve deleting \( R^+ \) facts already achieved beforehand. To avoid excessive overhead, we approximate this by recording, in a pre-process, which red facts may be deleted by moving each black variable, and prefer an action if none of its black preconditions may incur any such side effects.

2. Our second enhancement pertains to the DTG paths chosen for the black precondition variables in DAGPLANNING (after REDBLACKPLANNING has already selected the next action). The red outside conditions are by design all reached (contained in \( R \)), but we can prefer paths whose red outside conditions are “active”, i.e., true when executing the current red-black plan prefix in the real task. (E.g., if a capacity variable is red, then this will prefer loads/unloads that use the actual capacity instead of an arbitrary one.) In some special cases, non-active red outside conditions can be easily fixed by inserting additional supporting actions.

**Supported Features**

In contrast to previous years, a support for conditional effects is currently mandated. Since there is no straightforward adaptation of the red-black heuristics to the formalism that supports conditional effects, we have chosen here to compile them away. This was done by multiplying them out in the translation step. On one hand, this can lead to an exponential blow-up in the task representation size. On the other hand, it does not split up an operator application into a sequence of operator applications. Our decision was based on the speculation that the latter option could potentially decrease red-black plan applicability, one of the main advantages of the current red-black heuristics.
